## Decode<sub>-Remember</sub>

- The opcode specifies the instruction format in which the instruction is encoded.
- After decoding the binary code of the instruction, the processor knows what instruction and parameters it is dealing with.
- Example **ADDI**:
- Immediate instructions contain bits that are interpreted as numerical value that is retrieved using shifting operations.
  - 5 bit are enough to encode 32 registers.

immediate	rs1	funct3	rd	opcode
12 bit	5 bit	3 bit	5 bit	7 bit

## Execute

- The execution of every RISC-U instruction has a well-defined effect. It changes the state of the machine only at a specific location involving little data.
- At most two registers or one register and one memory location are modified by an instruction.
  - Every instruction modifies the PC.
  - Most instructions which modify **data** (another register or memory location) have trivial control flow (PC to next instruction).
  - Control-flow instructions have a more sophisticated **control flow**, that is, they may change the PC using relative or absolute addressing.

## Decoding Instructions

- Each instruction can be uniquely identified by certain parts of the 32 bits called opcode, funct3 and funct7 code.
- When the instruction is known, the meaning of the remaining bits of the instruction becomes clear.
